¹ The number of births per 1,000 population.

² The number of births per 1,000 women of childbearing age (15-44 years old).

³ The sum of age group-specific birth rates multiplied by the number of years in the age group (five years in this case). In Table 1B-1 rate of 2,388 in 1998 for example, means that if a hypothetical group of 1,000 women were to have the same birth rates in each age group that were observed in the actual childbearing population in 1998, they would have a total of 2,388 children by the time they reached the end of the reproductive period (taken here as age 50), assuming that all of the women survived to that age.

⁴ The sums of birth rates by 5-year age groups multiplied by the proportion of births that were female. The gross reproduction rate represents the average number of daughters born to a hypothetical cohort of 1,000 women if they experienced the age-specific birth rates observed in a given year throughout their childbearing years, and if none of the cohort was to die during her childbearing years. See Table 1B-2 for the annual proportions of births that were female in 1993-2003.

⁵ The number of births per 1,000 women in specified age group. For females under 15, the rate is calculated using the female population 10-14 years of age. For women over 44, the rate is calculated using the female population 45-49 years of age.

Note: The rates for 1993-1999 use population denominators projected from the 1990 census.
